
Questions about IntelliGen NCS network protocol

Hi Karl,

I'm working with SkyWater Technology on a project relating to their Entegris pump infrastructure for my university capstone. Scott Lindauer from SkyWater gave me your contact.

I've been working from the IntelliGen & InVue Communications Protocol spec, the SVID list for firmware, the public manual for NCS, etc. However there's a few questions I had after reading through these datasheets:

1. What is the byte order of the fields in the NCS protocol header? The serial comm to the pumps are specified as LSB, but the network header doesn't specify.
2. The response header's size field doesn't have a description in the spec. I'm assuming it follows the same convention as the command header, being the size of the entire packet including the header, would that be correct?
3. Does the COM1 on the NCS correspond to logical serial number 0 or 1?
4. Also, there are some code snippets in the docs for CRC calculation, RLC encoding, etc. so I was wondering if there are any other code snippets y'all can provide that might be helpful.

I appreciate any help you're able to provide.

Thanks,

Justus Languell
